ABSTRACT

An effective and convenient procedure for the Michael Addition using Fe (acac)₃ (5 mol %) as an effective catalyst, catalyses the Michael addition reaction of nitro methane to Chalcone to produce corresponding γ - nitro ketone derivatives with good yields (85-95 %) under mild condition with high yield. Accordingly, we applied this synthetic strategy for synthesis of (±)-Baclofen and (±)-Rolipram.

Reaction Conditions: a) Chalcone (0.82 mmol), Nitromethane (2) (4.10 mmol), 5 mol % Fe(acac)₃, anhy. DMSO (2mL), rt.

INTRODUCTION

The transition metal catalysis plays an important role in modern organic chemistry (Carsten *et al.*, 2004). The most of the reaction catalyzed by Lewis acid are stoichiometric therefore, recently great attention towards the transition metal catalyzed reaction in synthetic chemistry due to their numerous advantages low cost, nontoxic or interesting catalytic activity, reaction proceed cleanly with high efficiency and easy to handle, at ambient reaction condition without formation of salt. Although precious metal catalysts have their own impact on the field, alternatively non-precious metals like Cu, Co, Ce, Ni and Fe are emerging as important catalysts.

To access C-C bonds, novel transition metal complexes or salts have previously been used as catalysts. Iron is well known as one of the most abundant and cheapest metals. However, the use of Iron salt as important Lewis acid in organic transformation such as homo coupling (Allena *et al.*, 2009), Grignard reaction (Volla, 2008), alkylation (Cahiez, 1996), alkenylation of organo manganese (Seck *et al.*, 2004), aryl coupling reaction (Xu *et al.*, 2006), N-Arylation (Buchwald, 2009), C-N bond cleavage (Kuninobu *et al.*, 2010) and Michael addition (Christoffers *et al.*, 2000) *etc.* The Michael addition is the nucleophilic addition of carbanion to an α , β unsaturated conjugated double bond is one of the fundamental C-C bond forming reaction in organic synthesis (Ballini *et al.*, 2005). Among various nucleophiles, nitroalkanes have been demonstrated to be a valuable stabilized carbanion for the conjugate addition, due to the strong electron withdrawing

nature of the nitro group (Ono, 2001). Which represent a very important functionality in organic transformation due to its easily converted into elaborated functionalities in bioactive molecules such as amino carbonyls, aminoalcohols (Luzzio, 2001), Diketones (Ballini and Petrini, 2004) and pharmacologically active intermediates γ -lactams for synthesis of (R)-Baclofen (Corey *et al.*, 2000) and (R)-Rolipram (Peter *et al.*, 2008). Michael addition reactions usually carried out under strong basic (Kim *et al.*, 2010) or acidic condition (Moon *et al.*, 2001). There are few reports with transition metal Lewis acid (Cu, (Watanabe *et al.*, 1982) Zn, (Irie *et al.*, 1980) Co, (Schionato *et al.*, 1989) Ni (Comelles *et al.*, 2005) and Fe (Christoffers *et al.*, 2000) etc.) (II) Complexes and Mg-Al-O-*t*-Bu hydrotalcite (Choudary *et al.*, 2000) to the Michael addition reactions of nitro alkanes. These reaction suffering from some limitation such as harsh reaction condition, limiting the yield, high amount catalyst loading, particularly unsuitable for industrial and economical synthesis. Hence, we will wish to develop an efficient and environmentally acceptable synthetic method is an important task of modern chemistry, which can overcome some limitation associated with existing methodologies and extended scope of present methodology for synthesis of (±)-Rolipram and (±)-Baclofen via novel Baeyer Villiger reaction. The Baeyer Villiger oxidation is a widely used reaction for converting ketone to esters. The oxidizing agent that is generally used for the reaction is *m*-CPBA, and because this contains about 20% *m*-chlorobenzoic acid, it is safe to both store and use (Baeyer *et al.*, 1899). In recent years, some alternative methods are available for carrying out Baeyer Villiger reaction in their research laboratories (Ali *et al.*, 1976). In this communication, we also wish to report a novel and simple procedure for Baeyer Villiger reaction on γ - nitro ketone which includes H₂O₂ in AcOH (Horner *et al.*, 1973).

Experimental

MATERIALS AND METHODS

All reactions were carried out in dry solvents, unless otherwise stated. Reactions were monitored by thin layer chromatography (TLC) on silica gel plates (Kieselgel 60 F₂₅₄, Merck). Visualization of the spots on TLC plates was achieved either by UV light or by staining the plates in 2, 4-dinitrophenylhydrazine/ anisaldehyde and charring on hot plate. All products were characterized by ¹H NMR and ¹³C NMR, IR, Mass and Elemental analysis. ¹H NMR and ¹³C NMR were recorded on Varian Mercury 300 MHz spectrometer. Chemical shifts are expressed in ppm values and ¹H NMR spectra are referenced to 0.00 ppm for Me₄Si (TMS) and ¹³C NMR spectra are referenced to 77.00 ppm for CDCl₃. Peak multiplicities are designated by the following abbreviations: s, singlet; brs, broad singlet; d, doublet; t, triplet; q, quartet; m, multiplet; J, coupling constant in Hz. IR spectra were obtained on a Shimadzu FTIR-8400 with samples loaded as thin films on KBr plate, neat or with CH₂Cl₂ as indicated. Mass spectra were recorded at an ionization potential of 70 eV; Elemental analyses were recorded on Flash E. A. 1112 Thermo instrument. Melting points recorded are uncorrected. Column chromatography on silica gel (100-200 mesh) was performed with reagent grade ethyl acetate and hexane as an eluent.

Synthesis of the γ - nitro ketone derivatives

Typical experimental procedure

A mixture of chalcone (200 mg, 0.82 mmol), Fe(acac)₃ (5 mol %) in DMSO (2 mL) were stirred at room temperature. Nitro methane (4.00 mmol) was added and reaction mixture was further stirred for 1.0h. After completion of reaction the mixture was diluted with water. The reaction mixture was extracted with EtOAc (2 X 20mL) and organic layer was washed with brine and dried with Na₂SO₄. Evaporation of solvent furnished the crude product that was purified by column chromatography over silica gel using EtOAc in petroleum ether to give pure product. This procedure is followed for all the reactions listed in (Table 1). Known compounds and were identified by spectroscopic data (IR, ¹H, ¹³C NMR, GCMS) and are in good agreement with those of the reported. The spectroscopic and analytical data of new products whose spectroscopic data are not readily available are provided here in order of their below.

RESULTS AND DISCUSSION

As part of our ongoing research program herein, we wish to report on a new catalyst for Michael addition. However, we are first time demonstrating that the use of Fe(acac)₃ for Michael addition of Nitromethane **2** on Chalcone **1a** furnished the **3a** with good yield at ambient reaction condition in 1.0h (Scheme 1).

Scheme 1. ^a Reaction Conditions: a) Chalcone (0.82 mmol), Nitromethane(2) (4.10 mmol), 5 mol % Fe(acac)₃, anhy. DMSO (2mL), rt.

For optimization of reaction condition, screening of various solvents such as CHCl₃, CH₂Cl₂, EtOH, DMF, and DMSO. The reaction was carried out as shown in Scheme 1 and consequent results in Table 1. While in DMF and DMSO catalyze the reaction to provided in good yields in 1.0-1.5h, the other solvents provided lower yields under similar reaction condition.

We found that DMSO is having the yield of **3a** (90 %, entry 5) has been emerged as the most convenient solvent and DMF is also having the yield of **3a** (87 %, entry 4). It is interesting to note that (DMF and DMSO) are highly polar solvent and they have lack of the ability to form hydrogen bonding. But these solvents are still able to solvate cation by donating electron from oxygen. As a result of investigation several solvents, DMSO was found to be the most effective solvent for promoting favorable reaction condition and **3a** was obtained in 90 % yield.

Table 1. Solvent effect for the synthesis γ - nitro ketone

Entry	Solvent	Time (h)	Yield (%) ^b
1	CH ₂ Cl ₂	12.0	45
2	CHCl ₃	13.0	40
3	EtOH	8.5	75
4	DMF	1.5	87
5	DMSO	1.0	90

^aReaction Conditions: a) Chalcone (0.82 mmol), Nitromethane (4.10 mmol); 5 mol % Fe(acac)₃, solvents (2mL), rt ^b Isolated yield after purification; ^c acac = acetyl acetate, rt = room temp

Table 2. Effect of catalyst loading for synthesis of γ - nitro ketone

Entry	Mol%	Time (h)	Yield (%) ^b
1	10.0	1.0	83
2	5.0	1.0	90
3	1.0	1.0	86
4	0.5	1.0	70
5 ^c	0.0	1.0	--

^aReaction Conditions: a) Chalcone (0.82 mmol), Nitromethane (4.10 mmol) ; 5 mol % Fe(acac)₃, anhydrous DMSO (2mL) rt.; ^bIsolated yield after purification; ^c no reaction;

By choosing the reaction parameters as shown in (Scheme 1), we have studied the influence of amount of catalyst in DMSO as a solvent on yield of **3a**. It has been observed that, the model reaction did not initiate at all without a catalyst for 1.0 h in DMSO. The amount of catalyst used for this reaction was varied from 10 mol % to 0.5 mol %. As can be expected, by decreasing the amount catalyst loading from 10 mol % to 1 mol %; the yield of **3a** is approximating same. However, a very less (0.5 mol %) of catalyst gave less yield (70%, entry 4). The influence of the two experimental parameters (solvent and catalyst load) was studied and the experiment that probe to the scope of chalcone substrate as shown in (Scheme 2) and summarized in (Table 3) Both Electron donating and electron withdrawing substituent on Chalcone 1a-1j underwent clean reactions affording the desired product with high yield (85-95 %). The substituent on α phenyl ring of chalcone with electron withdrawing group such as chloro, nitro, proceeds at faster rate than those with electron donating group such as methoxy, Cyclopentaoxy etc. All products were characterized by spectroscopic data (IR, ¹H NMR, ¹³C NMR and Mass) with elemental analysis.

Table 3. Fe catalyzed Michael addition reaction of nitro methane to substituted Chalcone in DMSO

Entry	Reactant	R ₁	R ₂	Product	Time(h)	Yield(%) ^b

10	1j	H	4-Cl	3j	2.0	88

^aReaction Conditions: a) Chalcone (0.82 mmol), Nitromethane (4.10 mmol) and 5 mol % Fe(acac)₃, anhydrous DMSO (2mL), rt ^b Isolated yield after purification ; ^c3e new compound; ^d DMSO = Dimethyl Sulphoxide, acac = acetyl acetate, rt = room temp. Furthermore, Application of our methodologies was extended to the concise synthesis of (±)-Baclofen and (±)-Rolipram. The synthesis of (±)-Baclofen

(Scheme 3) started from (4-chlorophenyl)-1-(4-methoxyphenyl) prop-2-en-1-one. A mixture of (4-chlorophenyl)-1-(4-methoxyphenyl)prop-2-en-1-one **1e** and nitro methane in DMSO in presence of catalytic quantity (1 mol%) of Fe(acac)₃ to gives γ - nitro ketone **3e** in 85% yield. Baeyer-Villiger reaction on **3e** using H₂O₂ in AcOH to give corresponding γ - nitro ester **4**, the resulting nitro group can be reduced with sodium borohydride in presence of nickel chloride it resulted to generate a pyrrolidine moiety **5**. Finally, hydrolysis of pyrrolidine with HCl will lead to (±)-Baclofen as a neurotransmitter inhibitor drug molecule. Using this strategy, (±)-Baclofen was obtained in four steps with an overall of yield 53.55%. It is used therapeutically to treat spasms caused by spinal cord injury or disease.

Scheme 3. a) Chalcone **1e**(0.82 mmol), Nitromethane **2** (4.10 mmol), Fe(acac)₃, DMSO, 40 °C, 85%. b) H₂O₂, H₂SO₄, AcOH 60 °C, 90% c) NiCl₂.6H₂O, NaBH₄, MeOH, 30 min 0 °C - rt, 70%. d) 6N HCl, reflux, 24 h

Scheme 4. a) Chalcone (**0.82**), Nitromethane **2** (4.10 mmol), Fe(acac)₃, DMSO, 50 °C, 82%. b) H₂O₂, H₂SO₄, AcOH 60 °C, 92% c) NiCl₂.6H₂O, NaBH₄, MeOH, 30 min 0 °C - rt, 70%

We further interested to use present synthetic strategy for synthesis of (±)-Rolipram the novel synthetic route as represented in the Scheme 4. Accordingly, we subjected to chalcone **7** on iron catalyzed Michael addition of nitro methane to gives γ - nitro ketone **8** in 82 % yield. Baeyer-Villiger reaction on **8** using H₂O₂ in AcOH to offered corresponding γ -nitro ester **9**, followed by nickel catalyzed reduction of the nitro group with sodium borohydride in presence of nickel chloride to afford cyclic amide as a (±)-Rolipram act as

neurotransmitter inhibitor drug molecule. We have achieved a synthesis of (±)-Rolipram in three steps with an overall yield of 52.16%. A broad scope of Baeyer Villiger oxidation by H₂O₂ as the oxidant has been accomplished in the presence of AcOH. Here, we found that the relative migratory ability of the methoxy substituent attached to a carbonyl which converts ketone to ester easily.

The methoxy group stabilizes positive charge in Baeyer Villiger oxidation for formation of desired product within short time as compared to litt (Corey *et al.*, 2000) and by product *p*-hydroxy anisole **6** is an important starting material for synthesis of bioactive molecules (Suresh *et al.*, 2008).

Conclusion

In summary, we have developed an environmentally friendly Michael addition of nitro methane on different Chalcone in the presence of transition metal catalyst at ambient reaction condition without formation of salt. The methodology has been applied successfully synthesis of (±)-Rolipram and (±)-Baclofen *via* novel Baeyer Villiger reaction. An advantage of this synthetic strategy includes simple catalyst, mild reaction, shorter reaction times and easy work-up procedure.
